1 Installation

Some functions of WeightedCluster require the free GraphViz program (Gansner and North, 1999). It needs to be installed before launching R for these functions to work properly. You can download it here: http://www.graphviz.org.

The **WeightedCluster** library can be installed and loaded using the following commands:

```
R> install.packages("WeightedCluster")
R> library(WeightedCluster)
```

2 An illustrative example

In this preview, we use the dataset from McVicar and Anyadike-Danes (2002) which is distributed with the **TraMineR** library (Gabadinho *et al.*, 2011). This dataset contains sequences of school-to-work transitions in Northern Ireland. The dataset is loaded using:

```
R> data(mvad)
```

wcAggregateCases allows us to identify and aggregate identical state sequences (which are in columns 17:86). We print out the basic information about the aggregation and create the uniqueMvad object which contains only unique sequences.

```
R> aggMvad <- wcAggregateCases(mvad[, 17:86])
R> print(aggMvad)

Number of disaggregated cases: 712
Number of aggregated cases: 490
Average aggregated cases: 1.45
Average (weighted) aggregation: 1.45

R> uniqueMvad <- mvad[aggMvad$aggIndex, 17:86]</pre>
```

Using the unique sequence dataset, we build a sequence object and compute dissimilarities between sequences (see Gabadinho et al., 2011, for more on this topics). The vector aggMvad\$aggWeights store the number of replication of each unique sequence. It is thus used as unique sequence weight.

```
R> mvad.seq <- seqdef(uniqueMvad, weights=aggMvad$aggWeights)
R> ## Computing Hamming distance between sequence
R> diss <- seqdist(mvad.seq, method="HAM")</pre>
```

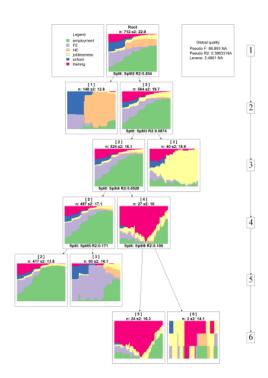

3 Hierarchical clustering

We can regroup similar sequences using hierarchical clustering with "average" method using weights (aggMvad\$aggWeights) (any method may be used).

```
R> averageClust <- hclust(as.dist(diss), method="average", members=aggMvad$aggWeights)
```

The agglomeration schedule can be represented graphically as a tree using:

```
R> averageTree <- as.seqtree(averageClust, seqdata=mvad.seq, diss=diss, nclus-
ter=6)
R> seqtreedisplay(averageTree, type="d", border=NA, showdepth=TRUE)
```

4 Cluster quality

We can automatically compute several clustering quality measures (presented in table 1) for a range of numbers of groups: 2 until ncluster=10.

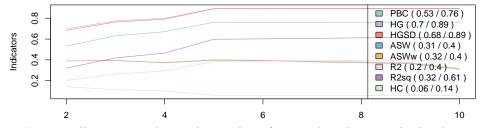

```
R> avgClustQual <- as.clustrange(averageClust, diss, weights=aggMvad$aggWeights, ncluster=10)
```

The results can be plotted and used to identify the best number of groups (you can also print them).

```
R> plot(avgClustQual)
```

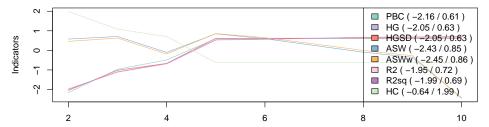

Table 1: Cluster Quality Measures Available in WeightedCluster

Table 1. Cluster Quanty Measures Avanable in Weighted Cluster				
Name	Abrv.	Range	Min/Max	Interpretation
Point Biserial Correlation	PBC	[-1; 1]	Max	Capacity of the clustering to reproduce the original distance matrix.
Hubert's Gamma	HG	[-1; 1]	Max	Capacity of the clustering to reproduce the original distance matrix (Order of magnitude).
Hubert's Somers D	HGSD	[-1; 1]	Max	Same as above, taking into account ties in the distance matrix.
Hubert's C	НС	[0; 1]	Min	Gap between the current quality of clustering and the best possible quality for this distance matrix and number of groups.
Average Silhouette Width	ASW	[-1; 1]	Max	Coherence of the assignments. A high coherence indicates high between groups distances and high intra group homogeneity.
Calinski- Harabasz index	СН	$[0; +\infty[$	Max	Pseudo F computed from the distances.
Calinski- Harabasz index	CHsq	$[0; +\infty[$	Max	Idem, using the $squared$ distances.
Pseudo \mathbb{R}^2	R2	[0; 1]	Max	Share of the discrepancy explained by the clustering.
Pseudo \mathbb{R}^2	R2sq	[0; 1]	Max	Idem, using the $squared$ distances.

It is usually easier to choose the number of groups based on standardized scores. Here, five groups seems to be a good solution.

R> plot(avgClustQual, norm="zscore")

Alternatively, we can retrieve the two best solutions according to each quality measure:

```
R> summary(avgClustQual, max.rank=2)
     1. N groups 1. stat 2. N groups 2. stat
PBC
             10
                 0.7617
                           9
                                      0.7614
HG
             10
                 0.8941
                                      0.8935
                 0.8912
HGSD
             10
                                      0.8906
              5
                 0.3969
                                  3
                                      0.3932
ASWw
             5
                 0.4014
                                  6
                                      0.3960
CH
              2 181.1067
                                  3 126.8778
R2
             10
                0.3982
                                  9
                                      0.3963
             2 335.8305
                                  5 262.6751
CHsq
             10
                 0.6148
                                  9
                                      0.6130
R2sq
             10
                  0.0598

                                      0.0599
```

5 PAM clustering

The **WeightedCluster** library also provides an optimized PAM algorithm. We can automatically compute PAM cluster for a range of numbers of groups using:

```
R> pamClustRange <- wcKMedRange(diss, kvals=2:10, weights=aggMvad$aggWeights)
```

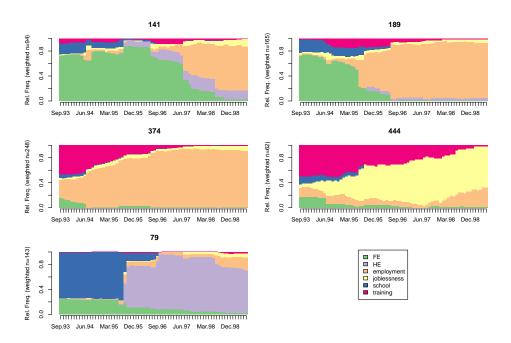

As before, we can plot the quality measures of each solution (not shown here) or retrieve the two best solutions according to each quality measure using:

```
R> summary(pamClustRange, max.rank=2)
     1. N groups 1. stat 2. N groups 2. stat
PBC
              2
                   0.619
                                   4
                                        0.618
                   0.845
HG
              10
                                   9
                                        0.845
HGSD
              10
                   0.842
                                   9
                                        0.842
ASW
              2
                   0.411
                                   9
                                        0.370
ASWw
              2
                   0.412
                                   9
                                        0.378
CH
              2 200.286
                                   3
                                      151.245
R2
              10
                   0.590
                                   9
                                        0.576
              2 394.893
                                      310.881

R2sq
              10
                    0.786
                                   9
                                         0.774
HC
                    0.100
                                   10
                                         0.104
```

6 Keeping a solution

The objets returned by as.clustrange or wcKMedRange contain a data.frame with cluster membership (named clustering). For instance, we can plot the sequences

R> seqdplot(mvad.seq, group=pamClustRange\$clustering\$cluster5, border=NA)

7 Disaggregating data

Once the sequences have been regrouped, it is often useful to "disaggregate" the data. For instance, we may want to add the cluster membership in the original data set (i.e. before unique sequences were identified). This allows us to crosstabulate cluster membership and father unemployment (variable funemp). This operation is performed using aggMvad\$disaggIndex which stores the index of each unique sequence in the original dataset.

```
R> uniqueCluster5 <- avgClustQual$clustering$cluster5
R> mvad$cluster5 <- uniqueCluster5[aggMvad$disaggIndex]
R> table(mvad$funemp, mvad$cluster5)

1 2 3 4 5
no 133 348 25 70 19
yes 14 69 16 10 8
```
